# INTERIM ENGINEERING REPORT <br> WATER SUPPLY DESIGN 

PREPARED FOR
Gore Developments Limited
2c Braemar Ave
Kingston 10

## GORE FLORENCE HALL DEVELOPMENT WATER SUPPLY DESIGN REPORT

### 1.0 OVERVIEW

Gore Limited proposes to develop lands north east of the Greenfield stadium and South of the North Coast Highway 2000 as a Housing Estate. The development will include a basic school, a commercial complex and several "green areas" which includes parks playfields and nature reverses.

The quantity of potable water required to sustain the proposed development is estimated to be $956 \mathrm{~m}^{3} /$ day. The estimate of water use required for the proposed development included quantities for domestic, commercial, basic school and for other social needs. As is advertised by the National Water Commission (NWC) municipal water is not intended for irrigation and this is excluded from the estimate of water use and is available from nearby infrastructure and service provider.

The proposed source of water for the development will be from NWC's Marthae brae station via a distribution pipe which runs parallel to the North Coast High. The documentation for the application for service will be provided by the Client.

## Water Distribution

## Water Quantity and Quality

The source of water to provide the required quantity and quality for the development is being handled by the Client who interacts directly with the WRA and Ministry of Health on this matter.

## Estimate of the development's potable water use

The present average number of persons per household based on the 2001 census is 3.6 however 4.5 is used to give a conservative population and estimate of water demand for the proposed development.

The peak factors were taken from the Jamaica Institution of Engineers recommended guidelines for design and construction of housing infrastructure volume 3 water supply systems.

Water losses on the distribution network were taken as 20\% of the estimated average day water demand as recommended by the NWC.

Table 1 Estimate of the Water Quantity required for the proposed Development

| Florence Hall Development |  |  |  |

| 45 | Employee/ Teacher/Student water demand | 57 | L/d |  |  |
| 46 |  |  |  |  |  |

## Water distribution network criteria

The service delivery standards for water distribution systems in Jamaica are set by the Office of Utilities Regulation. The recommended minimum pressure at the service connection during peak demand is $20 \mathrm{psi}(14 \mathrm{~m}$ of water or 138 kPa$)$. The Jamaica Institution of Engineers (JIE) Guidelines for Design and Construction of Housing Infrastructure recommend that the residual pressure at the hydrant during fire events be 5 psi ( 3.52 m of water or 34.47 kPa ). The water scheme was designed in accordance with the latest National Water Commission Developer's Manual requirements and water distribution models conform to AWWA M-31 Distribution system requirements for fire protection except for the pressure requirements which will be guided by the JIE guideline.

## Water distribution Network

The subdivision will be designed with varying sizes of PVC pipe ranging from of 250 mm to 50 mm diameter with the latter size serving a maximum of 16 lots. The network will be modelled to ensure that the minimum pressure will be 14 m of water (20psi) during peak demand (without fire flows).The network will be checked to ensure that a minimum pressure of $5 \mathrm{psi}(34 \mathrm{kPa}$ or 3.5 m of water) is maintained at hydrants when fire flows are drawn off the system while peak day demand flows are drawn off the system.

EPANET, a water distribution network analysis programme developed by the Water Supply and Water Resources Division (formerly the Drinking Water Research Division) of the U.S. Environmental Protection Agency's National Risk Management Research Laboratory, was used to size the distribution system. The Hazen-Williams method was used to determine the flows and pressures in the pipe network.

Figure 1 Water distribution model for the proposed Florence Hall Development showing node labels

Figure 1 shows the pipeline network layout and pressure at nodes during the peak hour flow and fire demand at node 68. This node was chosen as it is at the highest elevation and would represent the most critical location for fire flow. The Martha Brae system reservoir has a total head of 141.82 m and is able to deliver water to the Florence Hall area at pressures up to 100 m of water. The NWC supply line has been modelled as a reservoir set with total head of 70 m .

The water source is connected to the proposed development by a 200mm diameter pipeline at the entrance of the development. That water transmission main connects to $200 \mathrm{~mm}, 150 \mathrm{~mm}$ and 100 mm pipelines that loop through the proposed development.

The network was analysed to ensure that that the diurnal demands and minimum and maximum pressure requirements can be met throughout the life of the development and that the fire flow can be delivered throughout the proposed development. Fire flows were assigned to various nodes in the network at the highest and lowest elevations and other areas where it is likely to yield the limiting condition.

Figure 2 Water distribution model for the proposed Florence Hall Development showing pipe labels

Table 3 Results of the pressure variation in the water distribution model at peak flow with fire flow at node 68.

## Fire Flow Requirements

The fire flow requirements were guided by the AWWA Manual M31 Distribution system requirements for fire protection. The Jamaica Institution of Engineers recommended guidelines for design and construction of housing infrastructure volume 3 water supply systems allow the minimum pressure on the network during a fire to be 5 psi ( 34.5 kPa or 3.5 m of water). The required fire flow as defined in the manual is the rate of water flow, at a residual pressure of and for a specified duration, that is necessary to control a major fire in a specific structure. The residual pressure used in this report is 5 psi ( 34.5 kPa or 3.5 m of water) in the vicinity of the hydrant as allowed in the JIE guidelines.

The manual outlines a number of methods to assess the Needed Fire Flow (NFF) and duration. The values used in this report conform to the Insurance Services Office method.

The fire flow used for this project is two streams from a hydrant anywhere in the subdivision.

## Needed Fire Flow (NFF) for a dwelling in Florence Housing Development

The Insurance Services Office Method defines the NFF as the rate of flow considered necessary to control a major fire in a specific building. The calculation of a NFF, in US gallons per minute considers the construction $\left(\mathrm{C}_{i}\right)$, occupancy $\left(\mathrm{O}_{i}\right)$, exposure $\left(\mathrm{X}_{i}\right)$ and communication ( $\mathrm{P}_{i}$ ) factors of that building.

NFF $=\left(C_{i}\right)\left(O_{i}\right)(X+P)_{i}$
$\mathrm{C}_{i}=18 \mathrm{~F}\left(\mathrm{~A}_{i}\right)^{0.5}$
Where F = 1.0 for construction class 2 (jointed masonry)
$\mathrm{A}_{i}=$ effective area, where the effective area is the total square footage of the largest floor plus $50 \%$ of all other floors for class 2 construction

The effective area will be taken as $60 \%$ of a standard lot for a ground and a suspended floor. This is because the houses being sold can be expanded to this maximum.
$\mathrm{A}_{i}=3,600 \mathrm{sq} \mathrm{ft} \times 0.6 \times 1.5=3,240 \mathrm{sq} \mathrm{ft}$.
$\mathrm{C}_{i}=18 \times 1.0 \times(3,240)^{0.5}=1,024$ US gpm
$\mathrm{O}_{i}=0.82$ (From table 1-2 AWWA M31 limited combustible C-2)
$X_{i}=0.21$ (From table 1-3 AWWA M31)
$\mathrm{P}_{i}=0.3$ (From table 1-4 AWWA M31)
Therefore NFF $=1,024 \times 0.82 \times(0.21+0.3)=428.34$ US gpm or $1,621 \mathrm{Lpm}$ of 27 Lps
Two streams from a single hydrant can supply 30.4 Lps which will be adequate to suppress a fire from the building considered.

The fire flow used to check the distribution network is 31 Lps at selected hydrants.

## Water storage

Distribution storage can be economically justified if it takes care of normal daily variation and provide needed reserve for fire protection and minor emergencies.

The National Water Commission advised that the Martha Brae system includes transmission storage as such water storage is not needed to ensure the development is supplied with water regularly. Storage would only be needed during emergencies.

Table 5 Sizing of water storage tank

| Water Storage |  |  |
| :--- | ---: | :--- |
| JIE recommended $30 \%$ Ave day + fire qty | 571.22 | $\mathrm{~m}^{3} / \mathrm{d}$ |
|  | $\mathbf{1 5 0 , 9 0 0 . 1 5}$ | US gallons |
| One day's supply | $1,146.98$ | $\mathrm{~m}^{3} / \mathrm{d}$ |
|  | $\mathbf{3 0 3 , 0 0 0 . 4 9}$ | US gallons |

The Florence Hall site is not conducive to the siting of a tank. As such no tank is proposed for the development. If a tank were to be included in the civil infrastructure it would be located at the south end of the development. The appropriate size would be $1,135.624 \mathrm{~m}^{3}$ or $300,000 \mathrm{US}$ gallons.

## Water piping

1. PVC pipe shall conform to JS 39: Part 2: 1987 PVC plastic pipe SDR-PR. Part

2: Metric criteria for classifying PVC plastic pipes and requirements and methods of test for material, workman-ship, dimensions and pressure ratings.
2. PVC pipe designs to conform to methods described in Uni-Bell Handbook of PVC Pipe: Design and Construction.
3. Installation of PVC pressure pipe to conform to AWWA Standard C605, Underground Installation of Polyvinyl Chloride (PVC) Pressure Pipe and Fittings for Water.
4. Ductile iron pipe shall be designed in accordance with the latest revision of ANSI/AWWA C150/A21.50 for a minimum 150 psi (or project requirements, which ever is greater) rated working pressure plus a 100 psi surge allowance (if anticipated surge pressures are other than 100 psi , the actual anticipated pressure should be used); a 2 to 1 factor of safety on the sum of working pressure plus surge pressure; Type laying condition and a depth of cover of feet.
5. Sewer pipe construction to conform to ASTM Standard D2321, Standard Practice for Underground Installation of Thermoplastic Pipe for Sewers and other Gravity-Flow Applications.

## Conclusion

The water quantity requirements for the proposed development and network configuration proposed will adequately describe the sustainable infrastructure needs for the proposed development.
